BRENT VINE

RIG-VEDIC *VÁATA-* AND THE ANALYSIS OF METRICAL DISTRACTIONS

1. The "laryngeal theory"[1] is directly responsible for several important advances in our understanding of Vedic (and Avestan) versification. One of these concerns so-called metrical distractions, in which a transmitted long vowel or diphthong must be scanned not as a monosyllable, but as occupying two syllables: in many such cases, the scansion reflects a hiatus resulting from an earlier disyllabic sequence with intervocalic laryngeal; thus, to take the long-vowel case, (transmitted) *-ā-* < (IIr.) **-a'a-* < (IE) **-VHV-* or **-VHN̥-*, as in Ved. *bhā́s-* 'light' (often scanned *bháas-*) < IE **bheH-es-*.[2]

It has long been clear, however, that some distracted forms lacking a direct phonological source of this kind have been created analogically, typically on the basis of phonologically regular distracted forms elsewhere in the paradigm (or in similar paradigms). Thus the distracted scansion *giriṣṭháaḥ* (RV 9.18.1a, 9.62.4b, 9.98.9c) for the transmitted nom. sg. *giriṣṭhā́ḥ* 'living in the mountains' has been created analogically after the acc. sg. *giriṣṭháam* (RV 9.85.10b, transmitted *giriṣṭhā́m*), where the distraction is phonologically regular, given the intervocalic laryngeal in the accusative (IE **-steh$_2$-m̥*), but not in the nominative (IE **-steh$_2$-s*). Similarly, an "inter-paradigmatic" analogy has been invoked to explain forms like the imperative *paantu* (RV 4.4.12d; transmitted *pāntu*, to *pā-* 'protect', 3 sg. *pā́ti*), which may have been created analogically after paradigms like that of *átti* 'eats' (imperative *adántu*).[3]

In contrast to the above cases, consider a form like RV *dáasa-* (7x, to *dā́sa-* 'demon(ic), barbarian'), which is representative of a residue of forms with distracted root syllable for which there is no good evidence for phonological conditioning (i.e. a laryngeal-induced hiatus), and for which no paradigmatic (or "inter-paradigmatic") pressures can be found that may have conditioned an analogical distraction. How are we to explain metrical distraction in isolated forms of this kind?

2. The methodological and theoretical problems raised by the analysis of isolated distractions surface in a particularly clear way in E. Pirart's recent analysis of the distracted Rig-Vedic scansion *váata-* for *vā́ta-* 'wind'. In a discussion of the development of the Indo-European sequence **-eHn-* in Avestan,[4] Pirart has called into question both the distracted scansion *vā̃tāi*

Indo-Iranian Journal **33**: 267—275, 1990.
© 1990 *Kluwer Academic Publishers. Printed in the Netherlands.*

(Y. 44.4d) for Av. *vāta-* 'wind' (and thereby, together with his analyses of other Avestan forms, the validity of the generally-assumed treatment with hiatus of (preconsonantal) *-*eHn-* (i.e. *-*eHnC-*) > Av. *-a'a-*), as well as the antiquity of the distracted Rig-Vedic scansion *váata-* for *vā́ta-* 'id.'.[5] Pirart's argumentation (pp. 179—180) can be summarized as follows:

At Y. 44.4d (*kə̄ vātāi dvaṇmaibiiascā yaogəṯ āsū* (4 + 7)), Humbach reads trisyllabic *vā̃tāi*, "sans doute sur la foi de RS. *váata-*". But the Vedic scansion *váata-* is "très minoritaire" and "cantonnée à des parties récentes"; *váata-* is morphologically impossible anyway, since its presumed etymon *$h_2u\acute{e}h_1$-nt-o-* can only be explained as a thematized participle to an acrostatic *$h_2u\acute{e}h_1$-ti* ("type morphologique inconnu"). Morphologically preferable is *h_2ueh_1-to-*, which excludes (an original) Vedic *váata-*. Given, finally, an original RV *vā́ta-* < *h_2ueh_1-to-*, a trisyllabic Av. *vā̃tāi* is likewise impossible, and therefore the text must be emended to *kə̄ ˣuuātāi*, with a conjunctive particle *u*. These forms consequently provide no support for the treatment IE *-*eHn-* > Av. *-a'a-* (with hiatus).[6]

But nearly every step in this sequence is flawed, either methodologically or factually. Of fundamental importance, clearly, is the status of RV *váata-*: the rejection of this scansion as reflecting a laryngeal distraction largely determines Pirart's morphological analysis, on which, in turn, everything else depends. The Avestan emendation is gratuitous (the passage is clear as it stands, and does not require the additional particle), and seems motivated only by Pirart's wish to explain away the distracted scansion. We must first, therefore, examine RV *váata-*.

3. As for Pirart's observations on the scansion *váata-* ("c'en est là une métrique très minoritaire et cantonnée à des parties récentes de cette saṁhitā"); to begin with, the relative rarity of *váata-* (vis-à-vis *vā́ta-*) proves nothing by itself, and is in fact entirely consistent with archaism. It would acquire significance only if the second claim (regarding the restriction of this scansion to the later parts of the Rig-Veda) were true; we must begin, then, by evaluating this claim.

Pirart simply lists (with brief commentary) the cases traditionally read as *váata-*, in an excursus entitled "RS. *váata-* n'est pas ancien". In the absence of any explicit justification for this assertion (beyond the listing itself, together with several equivocal observations appended to it, to be discussed below), this stark claim would appear to derive solely from the fact that eight of the ten *váata-* cases are found in Books 1 and 10 of the Rig-Veda. In a general way, of course, such a correlation between "restriction to Books 1 and 10" and "lateness" has a well-known heuristic value, based on

its evident validity for a large number of features; but it is important to circumscribe the limitations of this correlation. In practice, the relative frequency of a given feature in Books 1 and 10 correlates with "lateness" only in the case of a large data base, since Books 1 and 10 both contain a certain amount of archaic material. With a small data base (as clearly with *váata-*), this sort of patterning has no significance of itself, unless the individual attestations in Books 1 and 10 can be shown to occur in late hymns on independent grounds. In point of fact, nearly all of the instances of *váata-* in Books 1 and 10 are found in archaic hymns.[7]

Pirart asserts that 10.23.4d (*úd íd dhūnoti vā́to yáthā vánam*) is "bricolé à partir de 5.78.8a" (*yáthā vā́to yáthā vánam*). But this is quite impossible; 10.23 belongs to the archaic Vimada collection (10.20—26), while 5.78.8 is the middle stanza of a patently late birth charm composed in Epic Anuṣṭubh.[8]

For 10.22.4a (*yujānó áśvā vā́tasya dhúnī*), in the same archaic collection, Pirart comments: "métrique isolée ARNOLD 1905, 231 paragr. 243, sinon obscure: ∪ — x — x, — — ∪ ∪ —. Corriger en *yujānó dhúnī, vā́tasyā́śvā*?" But Pirart's reference to Arnold is misleading, and the proposed emendation is entirely unnecessary, as will emerge from a closer look at the actual rhythm of the pāda, which is neither isolated nor obscure. What is "isolated" (as Arnold's discussion makes clear) is not the rhythm of 10.22.4a, but rather the particular stanza-form of this "uneven lyric" hymn, which shows a canonical form 11.8.8.8. Thus, with a distracted *váatasya*, the only quantitative irregularity in 10.22.4a is the short tenth syllable (i.e. the first syllable of *dhúnī #*). Short tenth syllable, however, is a metrical feature that is highly characteristic of the archaic period, especially when it falls on the initial syllable (as with *dhúnī #*) or the medial syllable of a word (see Arnold 204—6); 10.22.4a is thus metrically unexceptionable. Note further that a distracted *váatasya* produces the most regular quantitative sequence in the break after late caesura, whereas the non-distracted *vā́tasya* Pirart seems to advocate (both in his interpretation of the transmitted text and in his emendation) yields the least favored break rhythm after late caesura, with two consecutive long syllables (see Arnold 185).[9] Although decasyllabic variants do appear, in some stanzas of this hymn, in place of the normal eleven-syllable first pāda, there is not the slightest reason to *prefer* a decasyllabic interpretation (as Pirart's analysis would entail) when the distracted reading produces an acceptable eleven-syllable sequence.

A final argument against Pirart's emendation concerns the phrase *vā́tasyā́śvā*, which appears once again in the first pāda of the following stanza (10.22.5a, *tvā́ṃ tyā́ cid vā́tasyā́śvā*), and twice in other archaic hymns (see

next paragraph). It is difficult to believe (as Pirart seems to assume) that such an evidently traditional phrase would have been rearranged, in the transmission of 10.22.4a, so as to produce a (characteristically archaic) metrical irregularity. As for 10.22.5a; once again, a distracted *váatasya* produces the expected eleven-syllable sequence, whereas *vā́tasya* forces a needless decasyllabic interpretation.

The phrase *vā́tasyā́śvā* recurs in 1.174 and 1.175, which — like 10.22 — are Indra-hymns belonging to an archaic collection (1.165—191).[10] Strictly speaking, *vā́tasya* in 1.174.5b (*syūmanyū́ ṛjrā́ vā́tasyā́śvā*) need not be read as *váatasya*, since decasyllabic variations are relatively frequent in this hymn.[11] Similarly, in 1.175.4d (*kútsaṃ vā́tasyā́śvaiḥ*; Anuṣṭubh stanza), the syllabic interpretation is ambiguous (*vā́tasya áśuaiḥ*? *váatasyā́śuaiḥ*? catalectic, like 4c [*váhā śuṣṇāya vadhám*]? cf. Arnold 296). Nevertheless, there is no reason to favor a non-distracted interpretation in either of these cases, and it is simplest to assume that all of the archaic instances of this phrase preserve the same traditional distracted scansion.

Both of the other attestations in Book 1 are found in the same archaic collection. For 1.180.6c (*préṣad véṣad vā́to ná sūríḥ*), Pirart comments, "9 syllabes! Corriger en *véṣad u*?" But this comment is exceedingly difficult to interpret, since the line can in no way be taken to have nine syllables: *vā́to* must be read as distracted *váato*, producing a decasyllabic line of a type abundantly attested in this collection (compare also, in the same hymn, the slightly different decasyllabic pāda 3c *antár yád vaníno vām ṛtapsū*). The correction is thus unnecessary. In 1.186.10c (*adveṣó víṣṇur vā́ta ṛbhukṣā́ḥ*), as with 1.174.5b (above), the choice between distracted and non-distracted readings correlates with ambiguity between decasyllabic and hendecasyllabic interpretations; but there is again no reason to favor a decasyllabic interpretation. In contrast, note that the distracted reading in 1.180.6c ensures an obligatory decasyllabic interpretation.

For 10.158.1b (*vā́to antárikṣāt*), in a very late hymn, Pirart's comment "six syllabes!" is again obscure, since this is hardly a six-syllable line. Even admitting a scansion *vā́to* here (which Pirart's comment seems to advocate), the ablative singular is itself almost certainly distracted to *-aat* (as at least six times elsewhere in the Rig-Veda, cf. Arnold 99). Still, the seven-syllable line that would result is most unlikely for this hymn, and the line should simply be interpreted as an octosyllable *váato antárikṣaat*. In the two remaining instances, *váata-* appears in non-archaic (but not necessarily late) hymns, namely 7.40.6d (*vṛṣṭím párijmā vā́to dadātu*) and 9.97.52c (*bhradnáś cid átra vā́to ná jūtáḥ*). In neither case can *vā́to* be read without distraction, since this would produce decasyllables highly unlikely for 7.40, and all but

impossible for 9.97, which has no other certain decasyllabic pāda in all of its 58 stanzas.[12] These last three non-archaic cases, then, are clearly insufficient to call into question the archaic instances from Books 1 and 10 discussed above, and we may safely conclude that as far as the text of the Rig-Veda is concerned, "*váata-* est ancien".

4. If *vā́ta-*, as Pirart believes, was the original form, then the burden of explaining how *váata-* has arisen secondarily falls squarely upon his shoulders. He provides, however, no explanation, apart from the following observations appended to his list: "On remarque que la clausule est 4 fois *vā́tasyā́śva-*: RS. 1.174.5b 1.175.4d 10.22.4a (corrigé) et 10.22.5a; qu'on la retrouve en tête d'octosyllabe RS. 10.136.5a *vā́tasyā́śvo vāyóḥ sákhā* et que dans un hendécasyllabe ou un dodécasyllabe *váata-* suit chaque fois immédiatement la césure. Les cas de *vā́ta-* postcésural ayant un *-ā-* monosyllabique sont RS. 1.79.1b 4.38.3d 10.95.2d et 10.125.8a."

That a clausular *vā́tasyā́śva-* recurs (without distraction or hiatus) in the opening of a very late hymn composed in Epic Anuṣṭubh (10.136) is of very little interest, and explains nothing about how an original *vā́ta-* may have developed a distracted scansion *váata-*. More suggestive are the subsequent observations about the post-caesural position of *váata-* in eleven- and twelve-syllable lines, although the purport of these observations is not made clear. In fact, relatively frequent positioning of *váata-* after the caesura is precisely to be expected under the assumption that the distraction reflects an archaic variation.[13] Still, Pirart's observations could be taken as an attempt to explain away *váata-* as a secondary distraction starting from an original *vā́ta-*, with the restriction to post-caesural position somehow reflecting a purely metrical conditioning (perhaps related to an avoidance of the rare break pattern after late caesura noted above). If so, this would be a substantive theoretical claim (although not a very explicit one), which could be supported and to some extent tested by examining the behavior of other examples; these should ideally be phonotactically similar to *váata-*, since word shape would surely play a significant role in determining metrical position.

As a case in point, let us return to RV *dáasa-* (cf. §1 above), which is phonotactically (including accentually) similar to *váata-*, and which is said to occur with approximately equal rarity (7x; cf. Arnold's listing, p. 100). Rather strikingly, six of the seven occurrences (all in trimeter contexts) appear after caesura.[14] Moreover, all seven occurrences are found in archaic hymns with frequent syllabic variations (i.e. decasyllables in Triṣṭubh contexts, irregular hendecasyllables in Jagatī contexts), such that the distracted

readings are in fact never certain. These facts suggest that for some words, original decasyllabic sequences like # x x x x *dā́sam* x x x x # or # x x x x x *dā́sasya* x x # might have led to artificial distracted scansions *dáasam/dáasasya*, at a time when decasyllabic variations (and the corresponding, though rarer, shortened Jagatī variants) were passing out of use in favor of regularized and consistent Triṣṭubh and Jagatī patterns.

Thus, for some cases like *dā́sa-*, where there is no good evidence for assuming a laryngeal-induced distraction, and where any alleged distractions appear within the context of syllabic ambiguity arising from decasyllabic variations, there may well be a principled way of accounting for artificial secondary distractions, along the lines just suggested. Note further that for an isolated form like *dā́sa-*, where there is no paradigm-internal pressure that might help condition a distraction (as in the type [phonologically regular] acc. *giriṣṭháam* > [analogical] nom. *giriṣṭháaḥ*, cf. §1), a secondary "metrically-induced" distraction of the type outlined above cannot be conceived as having arisen *ex nihilo*: such a license can be understood only on the basis of previously-existing models, namely "real" cases in which the poetic language inherited by-forms precisely like *váata-/vā́ta-* (under the traditional interpretation). As for position in the line, word shape would surely play a significant role, as already mentioned; thus forms of *váata-/vā́ta-* (like *váatasya, váato*; cf. *dáasasya, dáasīḥ, dáasam*) would naturally be exceedingly useful in the break,[15] while forms of, say, *dáasvat-* (i.e. distracted forms of *dā́svat-* 'generous, liberal') would be most useful in the cadence: hence *dáasvān #* in trimeter (4.2.7d, 6.33.1b, 6.68.5c) and *dáasvatī #* (1.48.1d), *dáasvataḥ #* (5.9.2a) and *dáasvate #* (10.144.2b) in dimeter, these forms accounting for all but one of the distracted instances of *dā́svat-*.

But whereas *dáasa-* has strong metrical associations with decasyllabic (or similarly, in some cases, shortened Jagatī) contexts, the decasyllabic associations of *váata-* can be described as marginal or incidental: while some suspected instances of *váata-* are technically ambiguous by virtue of their appearance in decasyllabic contexts, other archaic instances show no such correlation, and in one case (1.180.6c) the distracted interpretation is necessary to ensure a decasyllabic pāda in an archaic hymn. We cannot so easily, then, explain *váata-* as having arisen secondarily in decasyllabic contexts, even if such a mechanism as that sketched above correctly accounts for cases like *dáasa-*. Finally, the fact that *váata-* is retained as an archaism (or at least a convenient metrical variant) in some late hymns (exactly as one would expect under the traditional interpretation), whereas *dáasa-* appears not to occur in late hymns, may or may not be significant. If this does not represent an accidental gap in attestation, it may well suggest

(as Arnold's metrical notes on the alleged *dáasa-* contexts generally imply) that an actual *dáasa-* had only the most tenuous existence (if it existed at all), and that most (or all) of the purported instances really reflect *dā́sa-* in decasyllabic (or shortened Jagatī) lines.

5. If, then, RV *váata-* is old, Pirart's morphological analysis becomes impossible: we must reinstate, in other words, not only RV *váata-*, but also its linguistic consequences, which are entirely consistent with the (by now widely accepted) analysis in terms of a thematized $*h_2\underset{\wedge}{u}\acute{e}h_1\text{-}\underset{\circ}{n}t\text{-}o$-, with secondary full-grade.[16] Since, moreover, Pirart's attempt to emend away the trisyllabic *vā̃tāi* at Y. 44.4d is not compelling, we may further conclude that for Avestan, the hiatus treatment *-*eHn-* > *-a'a-* remains possible, if not probable.[17]

In conclusion, the above examination of the methodology on which Pirart's claims are based goes beyond a re-evaluation of RV *váata-*, and leads to the following methodological corollary concerning the analysis of Rig-Vedic distractions: a claim that a distracted form is secondary (i.e. has a non-phonological source) calls for an explicit account of its origin. Traditionally, this has seemed most straightforward for inflectionally-related forms; but it is no less desirable — and in principle no less possible — to account for non-phonological distractions in isolated, extra-paradigmatic forms. The above remarks on *dáasa-* suggested a model according to which phonologically-based alternations like *váata-/vā́ta-* (and others with differing word shapes), together with the decasyllabic variations characteristic of a relatively early phase of Rig-Vedic composition, might help account for certain secondarily distracted forms. But the thorough elucidation of the dynamics of non-laryngeal distractions in the Rig-Veda remains a task for the future.[18]

NOTES

[1] For a good introduction, see F. O. Lindeman, *Introduction to the 'Laryngeal Theory'* (Oslo 1987).

[2] See in general Lindeman (above, n. 1) 44—6 and M. Mayrhofer, *Indogermanische Grammatik I.2* (Lautlehre) (Heidelberg 1986) 149, both with further references — for Indo-Iranian, especially the chapter "Hiatus caused by laryngeals" in M. V. Monna, *The Gathas of Zarathustra* (Amsterdam 1978) 97ff.

[3] Like *giriṣṭháaḥ* also verbal forms like *asthaat* (4x), *bhuut* (4x), etc. For the *paantu* type, see Lindeman (above, n. 1) 45—6 for references and discussion.

[4] *MSS* 47 (1986) 177—180, within an extended treatment of the development of laryngeals in Avestan ("Le traitement des laryngales intervocaliques en vieil-avestique métrique", 159ff.).

[5] For a listing of possible Vedic instances of *váata-*, see E. V. Arnold, *Vedic Metre in its Historical Development* (Cambridge 1905) 92, and for *váata-* as a reflection of the laryngeal hiatus resulting from an original *$h_2u\acute{e}h_1$-$n̥t$-o-*, see e.g. M. Mayrhofer (above, n. 2) 124, 149 n. 210, and R. S. P. Beekes, in A. Bammesberger (ed.), *Die Laryngaltheorie und die Rekonstruktion des indogermanischen Laut- und Formensystems* (Heidelberg 1988) 64—5; more hesitantly, for example, Lindeman (above, n. 1) 69 n. 55, 76 (with n. 61), with further references.

[6] On the basis of the verbal forms Av. *nąsat* (< *h_1ne-$h_1n\acute{k}et$*, redup. aor.) and *dąn* (< *$d(h)eh$-nt*, inj.), Pirart assumes the regular development to be *-*eHn-* > *-ān-*.

[7] In what follows, I will consider Arnold's rough relative dating of the hymns of the Rig-Veda (see esp. 269ff., 289ff.), based on his analyses of co-occurring metrical and linguistic features, to be sufficiently accurate to assist with evaluating the relative dating of the *váata-* attestations. There is admittedly an element of circularity introduced by the fact that Arnold used the distracted scansion *váata-* itself as one index (among many others) of relative chronology; but the designation "archaic" for the various hymns discussed below is always based on an evaluation of other criteria in addition to *váata-* itself, and never on *váata-* alone.

[8] On the metrically archaic technique of the Vimada hymns, see generally Arnold 170—1, 318—19; on the heptasyllabic variations in 10.26, see my remarks in *KZ* 91 (1977) 249—50.

[9] Indeed, the same observation applies to 10.23.4d (above), and to several other instances below. I return to this point in §4.

[10] According to Arnold (296), 1.174 (as also 1.186, cf. below) has "the archaic character more strongly marked than the rest of the hymns" in this collection.

[11] The same observation applies to *vā́to* in 10.23.4d (above), and to a somewhat lesser extent — despite Arnold's bracketing on p. 92 — to *vā́tasya* in 10.22.4a and 5a, since eleven-syllable sequences are favored in those contexts, as discussed above. See further below for more on the correlation with decasyllabic contexts.

[12] Even if, as Pirart thinks, 9.97.52c is "bricolé à partir de 4.17.12d *vā́to ná jū́tá stanáyadbhir abhraíḥ*" (which in this case is a distinct possibility), this fact of itself does not invalidate an archaic *váata-*; more on this point below.

[13] Cf. H. Hoenigswald, in A. Bammesberger (ed.), *Die Laryngaltheorie* (above, n. 5) 203: "The *vyūha* or metrical distraction (*-aam*, etc.) in Vedic Sanskrit . . . occurs especially near the caesura or at the cadence — the classical retentive locations". Note also that the instances of post-caesural *vā́ta-* cited by Pirart are found either in late hymns (10.95, 10.125), or in linguistically non-archaic hymns with only slight indications of metrical archaism (1.79, 4.38, partly also 10.95); in all cases, moreover, non-distracted *vā́ta-* appears after early caesura, thus producing a regular break rhythm (just as distracted *váata-* after late caesura produces a regular break rhythm, as discussed above).

[14] After early caesura: 6.26.5c, 10.49.6b, 7d (*dā́sam*), 2.20.7b (*dā́sīr*); after late caesura: 1.104.2c, 10.23.2d (*dā́sasya*). The exception is 6.20.10d, # x *dā́sīḥ*.

[15] Similar behavior, for example, with *náasatya-* (to *nā́satya-*), *aadityá-* (to *ādityá-*); cf. Arnold 99.

[16] Despite Pirart (cf. §2 above), the morphological analysis (on which see G. Darms, *Schwäher und Schwager, Hahn und Huhn: Die Vr̥ddhi-Ableitung im Germanischen* [Münich 1978] 396—7, with further references) need have nothing to do with an acrostatic present *$h_2u\acute{e}h_1$-ti*.

[17] In favor of *-*eHn-* >- *a'a-*, see most recently R. S. P. Beekes, *op. cit.* (above, n. 5), 69, and in *A Grammar of Gāthā-Avestan* (Leiden 1988) 89; A. Lubotsky, "Reflexes of Intervocalic Laryngeals in Sanskrit", paper presented at the 199th Meeting of the American Oriental Society, March 1989. As for the parallel case of RV *mā́s-*, Av. *må̄* (< *$méh_1n̥s$*)

'moon; month', Pirart's attempt to explain away the distracted scansion in Avestan (which appears in the same hymn as *vā̃tāi*: Y. 44.3d *kə̄ yā må̊*, 4-syll. hemistich) is again unsatisfactory; but a full discussion of the problems associated with this word, and with the remaining forms relevant to the development of **-eHn-* in Indo-Iranian (cf. n. 6 above), must be reserved for treatment elsewhere. It may be added, however, that Pirart (p. 178) quite correctly, in my view, rejects the single alleged Rig-Vedic instance of distracted scansion for *mā́s-* 'moon; month' (accepted, for example, by both Beekes and Lubotsky), namely 2.24.5b (*mādbhíḥ śarádbhir dúro varanta vaḥ*). As Pirart observes, the caesura prevents a reading *maadbhíḥ*, and the restitution of *ví* before *dúro* (Grassmann, Arnold) is very likely correct. (Compare also 3.32.9d *nā́hā ná mā́sāḥ śarádo varanta*.) The complete absence of distraction for RV *mā́s-* (14x), as also for thematic *mā́sa-* (7x), therefore remains problematic, despite the probable distracted Av. *må̊*.

[18] An earlier version of this paper was presented at the Eighth East Coast Indo-European Conference (University of North Carolina; May, 1988). I would like to express my gratitude to the participants of the Conference — and especially to Stephanie Jamison — for a number of helpful comments.
